## FEATURES <br> EASY TO USE

Gain Set with One External Resistor
(Gain Range 1 to 1000)
Wide Power Supply Range ( $\pm 2.3 \mathrm{~V}$ to $\pm 18 \mathrm{~V}$ )
Higher Performance than Three Op Amp IA Designs
Available in 8-Lead DIP and SOIC Packaging
Low Power, 1.3 mA max Supply Current
EXCELLENT DC PERFORMANCE ("B GRADE")
$50 \mu \mathrm{~V}$ max, Input Offset Voltage
$0.6 \mu \mathrm{~V} /{ }^{\circ} \mathrm{C}$ max, Input Offset Drift
1.0 nA max, Input Bias Current

100 dB min Common-Mode Rejection Ratio ( $G=10$ )
LOW NOISE
$9 \mathrm{nV} / \sqrt{\mathrm{Hz}}$, @ 1 kHz , Input Voltage Noise
$0.28 \mu \mathrm{~V}$ p-p Noise ( 0.1 Hz to 10 Hz )

## EXCELLENT AC SPECIFICATIONS

120 kHz Bandwidth (G = 100)
15 us Settling Time to 0.01\%

## APPLICATIONS

Weigh Scales
ECG and Medical Instrumentation
Transducer Interface
Data Acquisition Systems
Industrial Process Controls
Battery Powered and Portable Equipment

## PRODUCT DESCRIPTION

The AD620 is a low cost, high accuracy instrumentation amplifier that requires only one external resistor to set gains of 1 to

Figure 1. Three Op Amp IA Designs vs. AD620
REV. E

[^0]CONNECTION DIAGRAM
8-Lead Plastic Mini-DIP (N), Cerdip (Q) and SOIC (R) Packages

1000. Furthermore, the AD620 features 8-lead SOIC and DIP packaging that is smaller than discrete designs, and offers lower power (only 1.3 mA max supply current), making it a good fit for battery powered, portable (or remote) applications.

The AD620, with its high accuracy of 40 ppm maximum nonlinearity, low offset voltage of $50 \mu \mathrm{~V}$ max and offset drift of $0.6 \mu \mathrm{~V} /{ }^{\circ} \mathrm{C}$ max, is ideal for use in precision data acquisition systems, such as weigh scales and transducer interfaces. Furthermore, the low noise, low input bias current, and low power of the AD620 make it well suited for medical applications such as ECG and noninvasive blood pressure monitors.
The low input bias current of 1.0 nA max is made possible with the use of Super $\beta$ eta processing in the input stage. The AD620 works well as a preamplifier due to its low input voltage noise of $9 \mathrm{nV} / \sqrt{\mathrm{Hz}}$ at $1 \mathrm{kHz}, 0.28 \mu \mathrm{~V}$ p-p in the 0.1 Hz to 10 Hz band, $0.1 \mathrm{pA} / \sqrt{\mathrm{Hz}}$ input current noise. Also, the AD620 is well suited for multiplexed applications with its settling time of $15 \mu \mathrm{~s}$ to $0.01 \%$ and its cost is low enough to enable designs with one inamp per channel.

## THEORY OF OPERATION

The AD620 is a monolithic instrumentation amplifier based on a modification of the classic three op amp approach. Absolute value trimming allows the user to program gain accurately (to $0.15 \%$ at $G=100$ ) with only one resistor. Monolithic construction and laser wafer trimming allow the tight matching and tracking of circuit components, thus ensuring the high level of performance inherent in this circuit.
The input transistors Q1 and Q2 provide a single differentialpair bipolar input for high precision (Figure 33), yet offer 10x lower Input Bias Current thanks to Super $\beta$ eta processing. Feedback through the Q1-A1-R1 loop and the Q2-A2-R2 loop maintains constant collector current of the input devices Q1, Q2 thereby impressing the input voltage across the external gain setting resistor $\mathrm{R}_{\mathrm{G}}$. This creates a differential gain from the inputs to the $\mathrm{A} 1 / \mathrm{A} 2$ outputs given by $\mathrm{G}=(\mathrm{R} 1+\mathrm{R} 2) / \mathrm{R}_{\mathrm{G}}+1$. The unity-gain subtracter A3 removes any common-mode signal, yielding a single-ended output referred to the REF pin potential.
The value of $\mathrm{R}_{\mathrm{G}}$ also determines the transconductance of the preamp stage. As $R_{G}$ is reduced for larger gains, the transconductance increases asymptotically to that of the input transistors. This has three important advantages: (a) Open-loop gain is boosted for increasing programmed gain, thus reducing gainrelated errors. (b) The gain-bandwidth product (determined by C1, C2 and the preamp transconductance) increases with programmed gain, thus optimizing frequency response. (c) The input voltage noise is reduced to a value of $9 \mathrm{nV} / \sqrt{\mathrm{Hz}}$, determined mainly by the collector current and base resistance of the input devices.
The internal gain resistors, R1 and R2, are trimmed to an absolute value of $24.7 \mathrm{k} \Omega$, allowing the gain to be programmed accurately with a single external resistor.

The gain equation is then

$$
G=\frac{49.4 k \Omega}{R_{G}}+1
$$

so that

$$
R_{G}=\frac{49.4 k \Omega}{G-1}
$$

Make vs. Buy: A Typical Bridge Application Error Budget The AD620 offers improved performance over "homebrew" three op amp IA designs, along with smaller size, fewer components and $10 \times$ lower supply current. In the typical application, shown in Figure 34, a gain of 100 is required to amplify a bridge output of 20 mV full scale over the industrial temperature range of $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$. The error budget table below shows how to calculate the effect various error sources have on circuit accuracy.
Regardless of the system in which it is being used, the AD620 provides greater accuracy, and at low power and price. In simple
systems, absolute accuracy and drift errors are by far the most significant contributors to error. In more complex systems with an intelligent processor, an autogain/autozero cycle will remove all absolute accuracy and drift errors leaving only the resolution errors of gain nonlinearity and noise, thus allowing full 14-bit accuracy.
Note that for the homebrew circuit, the OP07 specifications for input voltage offset and noise have been multiplied by $\sqrt{2}$. This is because a three op amp type in-amp has two op amps at its inputs, both contributing to the overall input error.

Figure 35. A Pressure Monitor Circuit which Operates on a +5 V Single Supply

## Pressure Measurement

Although useful in many bridge applications such as weigh scales, the AD620 is especially suitable for higher resistance pressure sensors powered at lower voltages where small size and low power become more significant.
Figure 35 shows a $3 \mathrm{k} \Omega$ pressure transducer bridge powered from +5 V . In such a circuit, the bridge consumes only 1.7 mA . Adding the AD620 and a buffered voltage divider allows the signal to be conditioned for only 3.8 mA of total supply current.
Small size and low cost make the AD620 especially attractive for voltage output pressure transducers. Since it delivers low noise and drift, it will also serve applications such as diagnostic noninvasive blood pressure measurement.

## Medical ECG

The low current noise of the AD620 allows its use in ECG monitors (Figure 36) where high source resistances of $1 \mathrm{M} \Omega$ or higher are not uncommon. The AD620's low power, low supply voltage requirements, and space-saving 8-lead mini-DIP and SOIC package offerings make it an excellent choice for battery powered data recorders.
Furthermore, the low bias currents and low current noise coupled with the low voltage noise of the AD620 improve the dynamic range for better performance.
The value of capacitor C 1 is chosen to maintain stability of the right leg drive loop. Proper safeguards, such as isolation, must be added to this circuit to protect the patient from possible harm.

Figure 36. A Medical ECG Monitor Circuit

## Precision V-I Converter

The AD620, along with another op amp and two resistors, makes a precision current source (Figure 37). The op amp buffers the reference terminal to maintain good CMR. The output voltage $\mathrm{V}_{\mathrm{X}}$ of the AD620 appears across R1, which converts it to a current. This current less only, the input bias current of the op amp , then flows out to the load.

Figure 37. Precision Voltage-to-Current Converter (Operates on $1.8 \mathrm{~mA}, \pm 3 \mathrm{~V}$ )

## GAIN SELECTION

The AD620's gain is resistor programmed by $\mathrm{R}_{\mathrm{G}}$, or more precisely, by whatever impedance appears between Pins 1 and 8 . The AD620 is designed to offer accurate gains using $0.1 \%-1 \%$ resistors. Table II shows required values of $\mathrm{R}_{\mathrm{G}}$ for various gains. Note that for $G=1$, the $R_{G}$ pins are unconnected $\left(R_{G}=\infty\right)$. For any arbitrary gain $\mathrm{R}_{\mathrm{G}}$ can be calculated by using the formula:

$$
R_{G}=\frac{49.4 k \Omega}{G-1}
$$

To minimize gain error, avoid high parasitic resistance in series with $\mathrm{R}_{\mathrm{G}}$; to minimize gain drift, $\mathrm{R}_{\mathrm{G}}$ should have a low TC -less than $10 \mathrm{ppm} /{ }^{\circ} \mathrm{C}$-for the best performance.

Table II. Required Values of Gain Resistors

| $\mathbf{1 \%}$ Std Table <br> Value of $\mathbf{R}_{\mathbf{G}}, \boldsymbol{\Omega}$ | Calculated <br> Gain | $\mathbf{0 . 1 \%}$ Std Table <br> Value of $\mathbf{R}_{\mathbf{G}}, \boldsymbol{\Omega}$ | Calculated <br> Gain |

| 49.9 | 991.0 | 49.3 | 1,003 |

## INPUT AND OUTPUT OFFSET VOLTAGE

The low errors of the AD620 are attributed to two sources, input and output errors. The output error is divided by $G$ when referred to the input. In practice, the input errors dominate at high gains and the output errors dominate at low gains. The total $\mathrm{V}_{\mathrm{OS}}$ for a given gain is calculated as:

> Total Error RTI $=$ input error $+($ output error $/ \mathrm{G})$
> Total Error RTO $=$ (input error $\times \mathrm{G})+$ output error

## REFERENCE TERMINAL

The reference terminal potential defines the zero output voltage, and is especially useful when the load does not share a precise ground with the rest of the system. It provides a direct means of injecting a precise offset to the output, with an allowable range of 2 V within the supply voltages. Parasitic resistance should be kept to a minimum for optimum CMR.

## INPUT PROTECTION

The AD620 features $400 \Omega$ of series thin film resistance at its inputs, and will safely withstand input overloads of up to $\pm 15 \mathrm{~V}$ or $\pm 60 \mathrm{~mA}$ for several hours. This is true for all gains, and power on and off, which is particularly important since the signal source and amplifier may be powered separately. For longer time periods, the current should not exceed $6 \mathrm{~mA}\left(\mathrm{I}_{\mathrm{IN}} \leq\right.$ $\mathrm{V}_{\text {IN }} / 400 \Omega$ ). For input overloads beyond the supplies, clamping the inputs to the supplies (using a low leakage diode such as an FD333) will reduce the required resistance, yielding lower noise.

## RF INTERFERENCE

All instrumentation amplifiers can rectify out of band signals, and when amplifying small signals, these rectified voltages act as small dc offset errors. The AD620 allows direct access to the input transistor bases and emitters enabling the user to apply some first order filtering to unwanted RF signals (Figure 38), where $R C \approx 1 /(2 \pi f)$ and where $f \geq$ the bandwidth of the AD620; C $\leq 150 \mathrm{pF}$. Matching the extraneous capacitance at Pins 1 and 8 and Pins 2 and 3 helps to maintain high CMR.

Figure 38. Circuit to Attenuate RF Interference

## AD620

## COMMON-MODE REJECTION

Instrumentation amplifiers like the AD620 offer high CMR, which is a measure of the change in output voltage when both inputs are changed by equal amounts. These specifications are usually given for a full-range input voltage change and a specified source imbalance.

For optimal CMR the reference terminal should be tied to a low impedance point, and differences in capacitance and resistance should be kept to a minimum between the two inputs. In many applications shielded cables are used to minimize noise, and for best CMR over frequency the shield should be properly driven. Figures 39 and 40 show active data guards that are configured to improve ac common-mode rejections by "bootstrapping" the capacitances of input cable shields, thus minimizing the capacitance mismatch between the inputs.

Figure 39. Differential Shield Driver

Figure 40. Common-Mode Shield Driver

## GROUNDING

Since the AD620 output voltage is developed with respect to the potential on the reference terminal, it can solve many grounding problems by simply tying the REF pin to the appropriate "local ground."

In order to isolate low level analog signals from a noisy digital environment, many data-acquisition components have separate analog and digital ground pins (Figure 41). It would be convenient to use a single ground line; however, current through ground wires and PC runs of the circuit card can cause hundreds of millivolts of error. Therefore, separate ground returns should be provided to minimize the current flow from the sensitive points to the system ground. These ground returns must be tied together at some point, usually best at the ADC package as shown.

Figure 41. Basic Grounding Practice

## GROUND RETURNS FOR INPUT BIAS CURRENTS

Input bias currents are those currents necessary to bias the input transistors of an amplifier. There must be a direct return path for these currents; therefore, when amplifying "floating" input

Figure 42a. Ground Returns for Bias Currents with Transformer Coupled Inputs
sources such as transformers, or ac-coupled sources, there must be a dc path from each input to ground as shown in Figure 42. Refer to the Instrumentation Amplifier Application Guide (free from Analog Devices) for more information regarding in amp applications.
